(54) Title: NOVEL FORMS OF T CELLS COSTIMULATORY MOLECULES AND USES THEREFOR			
(57) Abstract <p>Novel structural forms of T cell costimulatory molecules are described. These structural forms comprise a novel structural domain or have a structural domain deleted or added. The structural forms correspond to naturally-occurring alternatively spliced forms of T cell costimulatory molecules or variants thereof which can be produced by standard recombinant DNA techniques. In one embodiment, the T cell costimulatory molecule of the invention contains a novel cytoplasmic domain. In another embodiment, the T cell costimulatory molecule of the invention contains a novel signal peptide domain or has an immunoglobulin variable region-like domain deleted. The novel structural forms of T cell costimulatory molecules can be used to identify agents which stimulate the expression of alternative forms of costimulatory molecules and to identify components of the signal transduction pathway which results in costimulation of T cells.</p>			

NOVEL FORMS OF T CELL COSTIMULATORY MOLECULES AND USES THEREFOR

Background of the Invention

5 For CD4+ T lymphocyte activation to occur, two distinct signals must be delivered by antigen presenting cells to resting T lymphocytes (Schwartz, R.H. (1990) *Science* 248:1349-1356; Williams, I.R. and Unanue, E.R. (1991) *J. Immunol.* 147:3752-3760; Mueller, D.L. et al., (1989) *J. Immunol.* 142:2617-2628). The first, or primary, activation signal is mediated physiologically by the interaction of the T cell receptor/CD3 complex
10 (TcR/CD3) with MHC class II-associated antigenic peptide and gives specificity to the immune response. The second signal, the costimulatory signal, regulates the T cell proliferative response and induction of effector functions. Costimulatory signals appear pivotal in determining the functional outcome of T cell activation since delivery of an antigen-specific signal to a T cell in the absence of a costimulatory signal results in functional
15 inactivation of mature T cells, leading to a state of tolerance (Schwartz, R.H. (1990) *Science* 248:1349-1356).

Molecules present on the surface of antigen presenting cells which are involved in T cell costimulation have been identified. These T cell costimulatory molecules include murine B7-1 (mB7-1; Freeman, G.J. et al., (1991) *J. Exp. Med.* 174:625-631), and the more recently
20 identified murine B7-2 (mB7-2; Freeman, G.J. et al., (1993) *J. Exp. Med.* 178:2185-2192). Human counterparts to the murine B7-1 and B7-2 molecules have also been described (human B7-1 (hB7-1) Freedman, A.S. et al., (1987) *J. Immunol.* 137:3260-3267; Freeman, G.J. et al., (1989) *J. Immunol.* 143:2714-2722; and human B7-2 (hB7-2); Freeman, G.J. et al., (1993) *Science* 262:909-911; Azuma, M. et al. (1993) *Nature* 366:76-79). The B7-1 and B7-
25 2 genes are members of the immunoglobulin gene superfamily.

B7-1 and B7-2 display a restricted pattern of cellular expression, which correlates with accessory cell potency in providing costimulation (Reiser, H. et al. (1992) *Proc. Natl. Acad. Sci. USA* 89:271-275; Razi-Wolf Z. et al., (1992) *Proc. Natl. Acad. Sci. USA* 89:4210-4214; Galvin, F. et al. (1992) *J. Immunol.* 149:3802-3808; Freeman, G.J. et al., (1993) *J. Exp.*
30 *Med.* 178:2185-2192). For example, B7-1 has been observed to be expressed on activated B cells, T cells and monocytes but not on resting B cells, T cells or monocytes, and its expression can be regulated by different extracellular stimuli (Linsley, P.S. et al., (1990) *Proc. Natl. Acad. Sci. USA* 87:5031-5035; Linsley, P.S. et al., (1991) *J. Exp. Med.* 174:561-569; Reiser, H. et al. (1992); *Proc. Natl. Acad. Sci. USA* 89:271-275; Gimmi, C.D. et al. (1991) *Proc. Natl. Acad. Sci. USA* 88:6575-6579; Koulouva, L. et al. (1991) *J. Exp. Med.* 173:759-762; Azuma, M. et al. (1993) *J. Exp. Med.* 177:845-850; Sansom, D.M. et al. (1993) *Eur. J. Immunol.* 23:295-298)

Both B7-1 and B7-2 are counter-receptors for two ligands, CD28 and CTLA4, expressed on T lymphocytes (Linsley, P.S. et al., (1990) *Proc. Natl. Acad. Sci. USA* 87:5031-

different cytoplasmic domains. The existence of alternative cytoplasmic domain forms of T cell costimulatory molecules supports a functional role for the cytoplasmic domain in transmitting an intracellular signal within a cell which expresses the costimulatory molecule on its surface. This indicates that costimulatory molecules not only trigger an intracellular signal in T cells, but may also deliver a signal to the cell which expresses the costimulatory molecule. This is the first evidence that the interaction between a costimulatory molecule on one cell and its receptor on a T cell may involve bidirectional signal transduction between the cells (rather than only unidirectional signal transduction to the T cell).

In yet another aspect of the invention, proteins that bind CD28 and/or CTLA4 and contain a novel signal peptide domain are provided. T cell costimulatory molecule genes which contain exons encoding different signal peptide domains which are used in an alternate manner have been discovered. Alternative splicing of mRNA transcripts of the gene can generate native T cell costimulatory molecules with different signal peptide domains. The existence of alternative signal peptide domain forms of T cell costimulatory molecules also suggests a functional role for the signal peptide of T cell costimulatory molecules.

Still another aspect of the invention pertains to isolated proteins that bind CD28 and/or CTLA4 in which a structural domain has been deleted or added, and isolated nucleic acids encoding such proteins. In a preferred embodiment, the protein (e.g., B7-1) has an immunoglobulin constant-like domain deleted (i.e., an immunoglobulin variable-like domain is linked directly to a transmembrane domain). In another embodiment, the protein has an immunoglobulin variable-like domain deleted (i.e., a signal peptide domain is linked directly to an immunoglobulin constant-like domain).

An isolated nucleic acid molecule of the invention can be incorporated into a recombinant expression vector and transfected into a host cell to express a novel structural form of a T cell costimulatory molecule. The isolated nucleic acids of the invention can further be used to create transgenic and homologous recombinant non-human animals. The novel T cell costimulatory molecules provided by the invention can be used to trigger a costimulatory signal in a T lymphocyte. These molecules can further be used to raise antibodies against novel structural domains of costimulatory molecules. The novel T cell costimulatory molecules of the invention can also be used to identify agents which stimulate the expression of alternative forms of costimulatory molecules and to identify components of the signal transduction pathway induced in a cell expressing a costimulatory molecule in response to an interaction between the costimulatory molecule and its receptor on a T lymphocyte.

Brief Description of the Drawings

Figure 1 is a photograph of an agarose gel depicting the presence of mB7-1 cytoplasmic domain II-encoding exon 6 in mB7-1 cDNA, determined by nested Reverse Transcriptase Polymerase Chain Reaction (RT-PCR).

disclosed forms of T cell costimulatory molecules, e.g., forms which result from alternative splicing of a primary mRNA transcript of a gene encoding a T cell costimulatory molecule.

Accordingly, one aspect of the invention relates to isolated nucleic acids encoding T cell costimulatory molecules corresponding to naturally-occurring alternatively spliced forms or variants thereof, and uses therefor. Another aspect of the invention pertains to novel structural forms of T cell costimulatory molecules which are produced by transcription and translation of the nucleic acid molecules of the invention, and uses therefor. This invention further pertains to isolated nucleic acids encoding novel structural domains of T cell costimulatory molecules, isolated polypeptides encoded therein, and uses therefor.

The various aspects of this invention are described in detail in the following subsections. Forming part of the present disclosure is the appended Sequence Listing. The numerous nucleotide and amino acid sequences presented in the Sequence Listing are summarized below.

- 15 SEQ ID NO: 1 - nucleotide sequence of mouse B7-1 exons 1-2-3-4-6
- SEQ ID NO: 2 - amino acid sequence of mouse B7-1 protein encoded by exons 1-2-3-4-6
- SEQ ID NO: 3 - nucleotide sequence of mouse B7-1 exons 1-2-3-4-5-6
- SEQ ID NO: 4 - nucleotide sequence of mouse B7-1 exon 6 (CytII)
- SEQ ID NO: 5 - amino acid sequence of mouse B7-1 peptide encoded by exon 6 (CytII)
- 20 SEQ ID NO: 6 - nucleotide sequence of mouse B7-1 full-length exon 1
- SEQ ID NO: 7 - nucleotide sequence of mouse B7-1 promoter
- SEQ ID NO: 8 - nucleotide sequence of B7-1 exons 1-3-4-5
- SEQ ID NO: 9 - amino acid sequence of mB7-1 protein encoded by exons 1-3-4-5
- SEQ ID NO: 10 - nucleotide sequence of mouse B7-1 exons 1-3-4-6
- 25 SEQ ID NO: 11 - amino acid sequence of mouse B7-1 protein encoded by exons 1-3-4-6
- SEQ ID NO: 12 - nucleotide sequence of mouse B7-2 exons m1B-2-3-4-5
- SEQ ID NO: 13 - amino acid sequence of mouse B7-2 protein encoded by exons m1B-2-3-4-5
- SEQ ID NO: 14 - nucleotide sequence of mouse B7-2 exon m1B
- SEQ ID NO: 15 - amino acid sequence of mouse B7-2 peptide encoded by exon m1B
- 30 SEQ ID NO: 16 - nucleotide sequence of mouse B7-1 exons 1-2-3-4-5 (as disclosed in Freeman, G. J. et al. (1991) *J. Exp. Med.* 174:625-631)
- SEQ ID NO: 17 - amino acid sequence of mouse B7-1 protein encoded by exons 1-2-3-4-5
- SEQ ID NO: 18 - nucleotide sequence of human B7-1 exons 1-2-3-4-5 (as disclosed in Freeman, G.J. et al. (1989) *J. Immunol.* 143:2714-2722)
- 35 SEQ ID NO: 19 - amino acid sequence of human B7-1 protein encoded by exons 1-2-3-4-5
- SEQ ID NO: 20 - nucleotide sequence of mouse B7-2 exons m1A-2-3-4-5 (as disclosed in Freeman, G.J. et al. (1993) *J. Exp. Med.* 178:2185-2192)
- SEQ ID NO: 21 - amino acid sequence of mouse B7-2 protein encoded by exons m1A-2-3-4-5

and RNA and can be either double stranded or single stranded. Preferably, the isolated nucleic acid molecule is a cDNA.

A. Nucleic Acids Encoding Novel Cytoplasmic Domains

5 One aspect of the invention pertains to isolated nucleic acids that encode T cell costimulatory molecules, each containing a novel cytoplasmic domain. It has been discovered that a gene encoding a costimulatory molecule can contain multiple exons encoding different cytoplasmic domains. In addition, naturally-occurring mRNA transcripts have been discovered which encode different cytoplasmic domain forms of T cell
10 costimulatory molecules. Thus, one embodiment of the invention provides an isolated nucleic acid encoding a protein which binds CD28 or CTLA4 and comprises a contiguous nucleotide sequence derived from at least one T cell costimulatory molecule gene. In this embodiment, the nucleotide sequence can be represented by a formula A-B-C-D-E, wherein

15 A comprises a nucleotide sequence of at least one first exon encoding a signal peptide domain,

B comprises a nucleotide sequence of at least one second exon of a T cell costimulatory molecule gene, wherein the at least one second exon encodes an immunoglobulin variable region-like domain,

20 C comprises a nucleotide sequence of at least one third exon of a T cell costimulatory molecule gene, wherein the at least one third exon encodes an immunoglobulin constant region-like domain,

D comprises a nucleotide sequence of at least one fourth exon of a T cell costimulatory molecule gene, wherein the at least one fourth exon encodes a
25 transmembrane domain, and

E comprises a nucleotide sequence of at least one fifth exon of a T cell costimulatory molecule gene, wherein the at least one fifth exon encodes a cytoplasmic domain,

30 with the proviso that E does not comprise a nucleotide sequence encoding a cytoplasmic domain selected from the group consisting of SEQ ID NO:25 (mB7-1), SEQ ID NO:27 (hB7-1), SEQ ID NO:29 (mB7-2) and SEQ ID NO:31 (hB7-2).

In the formula, A, B, C, D, and E are contiguous nucleotide sequences linked by phosphodiester bonds in a 5' to 3' orientation from A to E. According to the formula, A can
35 be a nucleotide sequence of an exon which encodes a signal peptide domain of a heterologous protein which efficiently expresses transmembrane or secreted proteins, such as the oncostatin M signal peptide. Preferably, A comprises a nucleotide sequence of at least one exon which encodes a signal peptide domain of a T cell costimulatory molecule gene. It is

cytoplasmic domain of the T cell costimulatory molecule. Additionally, a second, alternative cytoplasmic domain of another T cell costimulatory molecule is likely to be homologous to the Cyt II domain of mB7-1. For example, the first cytoplasmic domains of mB7-1, hB7-1, mB7-2 and hB7-2 display between 4 % and 26 % amino acid identity (see Freeman, G.J. et al. (1993) *J. Exp. Med.* 178:2185-2192). Accordingly, in one embodiment, an alternative cytoplasmic domain of a T cell costimulatory molecule has an amino acid sequence that is at least about 5 % to 25 % identical in sequence with the amino acid sequence of mB7-1 Cyt II (shown in SEQ ID NO: 5).

Another embodiment of the invention provides an isolated nucleic acid encoding a protein which binds CD28 or CTLA4 and is encoded by a T cell costimulatory molecule gene having at least one first exon encoding a first cytoplasmic domain and at least one second exon encoding a second cytoplasmic domain. The at least one first cytoplasmic domain exon of the gene comprises a nucleotide sequence selected from the group consisting of a nucleotide sequence of SEQ ID NO:25 (mB7-1), SEQ ID NO:27 (hB7-1), SEQ ID NO:29 (mB7-2) and SEQ ID NO:31 (hB7-2). In this embodiment, the isolated nucleic acid includes a nucleotide sequence encoding at least one second cytoplasmic domain. Preferably, the isolated nucleic acid does not comprise a nucleotide sequence encoding a first cytoplasmic domain (i.e., the nucleic acid comprises an alternative splice form of a transcript of the gene in which the exon encoding the first cytoplasmic domain, e.g., exon 5, has been excised from the transcript). Preferred T cell costimulatory molecule genes from which nucleotide sequences can be derived include B7-1 and B7-2.

In yet another embodiment, the isolated nucleic acid of the invention encodes a protein which binds CD28 or CTLA4 and comprises a nucleotide sequence shown in SEQ ID NO: 1. This nucleotide sequence corresponds to a naturally-occurring alternatively spliced form of mB7-1 which includes the nucleotide sequences of exons 1-2-3-4-6. Alternatively, the isolated nucleic acid comprises a nucleotide sequence shown in SEQ ID NO: 3, which corresponds to a naturally-occurring alternatively spliced form of mB7-1 comprising the nucleotide sequences of exons 1-2-3-4-5-6.

30 B. Nucleic Acids Encoding Novel Signal Peptide Domains

Other aspects of this invention pertain to isolated nucleic acids which encode T cell costimulatory molecules containing novel signal peptide domains. It has been discovered that a gene encoding a costimulatory molecule can contain multiple exons encoding different signal peptide domains and that mRNA transcripts occur in nature which encode different signal peptide domain forms of T cell costimulatory molecules. Thus, isolated nucleic acids which encode proteins which bind CD28 or CTLA4 and comprise contiguous nucleotide sequences derived from at least one T cell costimulatory molecule gene are within the scope of this invention. The nucleotide sequence can be represented by a formula A-B-C-D-E, wherein

In yet another embodiment of the invention, the isolated nucleic acid encodes a protein which binds CD28 or CTLA4 and is encoded by a T cell costimulatory molecule gene having at least one first exon encoding a first signal peptide domain and at least one second exon encoding a second signal peptide domain. The at least one first exon comprises a nucleotide sequence selected from the group consisting of a nucleotide sequence of SEQ ID NO:33 (mB7-1), SEQ ID NO:35 (hB7-1), SEQ ID NO:37 (mB7-2) and SEQ ID NO:39 (hB7-2) and SEQ ID NO:41 (hB7-2). In this embodiment, the isolated nucleic acid includes a nucleotide sequence encoding at least one second signal peptide domain. Preferably, the isolated nucleic acid does not comprise a nucleotide sequence encoding the first signal peptide domain (i.e., the nucleic acid comprises an alternative splice form of a transcript of the gene in which the exon encoding a first signal domain has been excised from the transcript). Preferred T cell costimulatory molecule gene from which nucleotide sequences can be derived include B7-1 and B7-2.

15 *C. Nucleic Acids Encoding Proteins With Domains Deleted or Added*

Another aspect of the invention pertains to isolated nucleic acids encoding T cell costimulatory molecules having structural domains which have been deleted or added. This aspect of the invention is based, at least in part, on the discovery that alternative splicing of mRNA transcripts encoding T cell costimulatory molecules generates transcripts in which an exon encoding a structural domain has been excised or in which at least two exons encoding two forms of a structural domain are linked in tandem. In one embodiment, the nucleic acid is one in which an exon encoding an IgV-like domain has been deleted (i.e., the signal peptide domain exon is linked directly to the IgC-like domain exon). Accordingly, in one embodiment, the isolated nucleic acid encodes a protein comprising a contiguous nucleotide sequence derived from at least one T cell costimulatory molecule gene, the nucleotide sequence represented by a formula A-B-C-D, wherein

30 A comprises a nucleotide sequence of at least one first exon of a T cell costimulatory molecule gene, wherein the at least one first exon encodes a signal peptide domain,

B comprises a nucleotide sequence of at least one second exon of a T cell costimulatory molecule gene, wherein the at least one second exon encodes an immunoglobulin constant region-like domain,

35 C comprises a nucleotide sequence of at least one third exon of a T cell costimulatory molecule gene, wherein the at least one third exon encodes a transmembrane domain, and

D comprises a nucleotide sequence of at least one fourth exon of a T cell costimulatory molecule gene, wherein the at least one fourth exon encodes a cytoplasmic domain.

cytoplasmic domain of mB7-1. The amino acid sequence of the protein encoded by this nucleic acid is shown in SEQ ID NO: 65. Naturally-occurring mRNA transcripts encoding murine B7-1 have been detected in which the exon encoding the IgC-like domain (i.e., exon 3) has been excised and the exon encoding the IgV-like domain (i.e., exon 2) is spliced to the exon encoding the transmembrane domain (i.e., exon 4) (see Example 7). When expressed in a host cell, the IgV-like isoform of mB7-1 is capable of binding to both mouse CTLA4 and mouse CD28 and can trigger a costimulatory signal in a T cell such that the T cell proliferates and produces interleukin-2 (see Example 7).

Yet another aspect of this invention features an isolated nucleic acid encoding a T cell costimulatory molecule which contains exons in addition to a known or previously identified form of the T cell costimulatory molecule. For example, a naturally-occurring murine B7-1 mRNA transcript has been identified which contains two cytoplasmic domain-encoding exons in tandem, i.e., the transcript contains exons 1-2-3-4-5-6 (the nucleotide sequence of which is shown in SEQ ID NO: 3). Since there is an in-frame termination codon within exon 5, translation of this transcript produces a protein which contains only the Cyt I cytoplasmic domain. However, if desired, this termination codon can be mutated by standard site-directed mutagenesis techniques to create a nucleotide sequence which encodes an mB7-1 protein containing both a Cyt I and a Cyt II domain in tandem.

II. Isolation of Nucleic Acids of the Invention

An isolated nucleic acid having a nucleotide sequence disclosed herein can be obtained by standard molecular biology techniques. For example, oligonucleotide primers suitable for use in the polymerase chain reaction (PCR) can be prepared based upon the nucleotide sequences disclosed herein and the nucleic acid molecule can be amplified from cDNA and isolated. At least one oligonucleotide primer should be complimentary to a nucleotide sequence encoding an alternative structural domain. It is even more preferable that at least one oligonucleotide primer span a novel exon junction created by alternative splicing. For example, an oligonucleotide primer which spans the junction of exon 4 and exon 6 can be used to preferentially amplify a murine B7-1 cDNA that contains the second, alternative cytoplasmic domain (e.g., a cDNA which contains exons 1-2-3-4-6; SEQ ID NO: 1). Alternatively, an oligonucleotide primer complimentary to a nucleotide sequence encoding a novel alternative structural domain can be used to screen a cDNA library to isolate a nucleic acid of the invention.

Isolated nucleic acid molecules having nucleotide sequences other than those specifically disclosed herein are also encompassed by the invention. For example, novel structural forms of B7-1 from species other than mouse are within the scope of the invention (e.g., alternatively spliced forms of human B7-1). Likewise, novel structural forms of B7-2 from species other than mouse are also within the scope of the invention (e.g., alternatively spliced forms of human B7-2). Furthermore, additional alternatively spliced forms for

or a portion of a nucleotide sequence encoding the costimulatory molecule (e.g., having all or a portion of a nucleotide sequence shown in SEQ ID NO: 16, 18, 20, 22 and 24). For costimulatory molecules whose genes have been mapped to a particular chromosome, a chromosome-specific library rather than a total genomic DNA library can be used. For example, hB7-1 has been mapped to human chromosome 3 (see Freeman, G.J. et al. (1992) *Blood* 79:489-494; and Selvakumar, A. et al. (1992) *Immunogenetics* 36:175-181. Genomic clones can be sequenced by conventional techniques and novel exons identified. A probe corresponding to a novel exon can then be used to detect the nucleotide sequence of this exon in mRNA transcripts encoding the costimulatory molecule (e.g., by screening a cDNA library or by PCR).

A more preferred approach for identifying and isolating nucleic acid encoding a novel structural domain of a T cell costimulatory molecule is by "exon trapping". Exon trapping is a technique that has been used successfully to identify and isolate novel exons (see e.g. Duyk, G.M. et al. (1990) *Proc. Natl. Acad. Sci. USA* 87:8995-8999; Auch, D. and Reth, M. (1990) *Nucleic Acids Res.* 18:6743-6744; Hamaguchi, M. et al. (1992) *Proc. Natl. Acad. Sci. USA* 89:9779-9783; and Krizman, D.B and Berget, S.M. (1993) *Nucleic Acids Res.* 21:5198-5202). The approach of exon trapping can be applied to the isolation of exons encoding novel structural domains of T cell costimulatory molecules, such as a novel alternative cytoplasmic domain of human B7-1, as described in Example 5.

In addition to the isolated nucleic acids encoding naturally-occurring alternatively spliced forms of T cell costimulatory molecules provided by the invention, it will be appreciated by those skilled in the art that nucleic acids encoding variant alternative forms, which may or may not occur naturally, can be obtained using standard recombinant DNA techniques. The term "variant alternative forms" is intended to include novel combinations of exon sequences which can be created using recombinant DNA techniques. That is, novel exons encoding structural domains of T cell costimulatory molecules, either provided by the invention or identified according to the teachings of the invention, can be "spliced", using standard recombinant DNA techniques, to other exons encoding other structural domains of the costimulatory molecule, regardless of whether the particular combination of exons has been observed in nature. Thus, novel combinations of exons can be linked *in vitro* to create variant alternative forms of T cell costimulatory molecules. For example, the structural form of murine B7-1 which has the signal peptide domain directly joined to the IgC-like domain (ie., which has the IgV-like domain deleted) has been observed in nature in combination with the cytoplasmic domain encoded by exon 5. However, using conventional techniques, an alternative structural form can be created in which the IgV-like domain is deleted and the alternative cytoplasmic domain is encoded by exon 6. In another example, a murine B7-1 cDNA containing exons 1-2-3-4-5-6 can be mutated by site-directed mutagenesis to change a stop codon in exon 5 to an amino acid encoding-codon such that an mB7-1 protein can be produced which contains both a Cyt I domain and a Cyt II domain in tandem. Additionally,

forms of T cell costimulatory molecules having a nucleotide sequence which differs from those provided herein due to degeneracy of the genetic code are considered to be within the scope of the invention.

5 III. Additional Isolated Nucleic Acid Molecules of the Invention

 In addition to isolated nucleic acids encoding alternative forms of T cell costimulatory molecules, the invention also discloses previously undescribed nucleotide sequences of the murine B7-1 gene and mRNA transcripts. As described in detail in Example 3, it has now been discovered that murine B7-1 mRNA transcripts contain additional 5' untranslated (UT) sequences which were not previously reported. A 5' UT region of approximately 250 base
10 pairs has been reported for mB7-1 mRNA transcripts, determined by primer extension analysis (see Selvakumar et al. (1993) *Immunogenetics* 38:292-295). As described herein, an additional ~1500 nucleotides of 5' UT sequences have been discovered in mB7-1. These 5' UT sequences are contiguous with known exon 1 sequences, thereby extending the size of
15 exon 1 by approximately 1500 base pairs. Thus the novel 5' UT sequence of the invention corresponds to the 5' region of mB7-1 exon 1 (i.e., exon 1 extends an additional ~1500 nucleotides at its 5' end than previously reported) rather than corresponding to a new exon upstream of exon 1. Computer analysis of the potential secondary structure of the 5' UT region reveals that the most stable structure is comprised of multiply folded palindromic
20 sequences. This high degree of secondary structure may explain the results of Selvakumar et al. ((1993) *Immunogenetics* 38:292-295) in that the secondary structure could account for premature termination of the primer extension reaction. The potential for excessive secondary structure in the 5' UT region suggests that post-transcriptional mechanisms are involved in controlling mB7-1 expression. Thus, inclusion of the long 5' UT sequence in
25 recombinant expression vectors encoding mB7-1 may provide post-transcriptional regulation that is similar to that of the endogenous gene. Accordingly, the 5' UT region of mB7-1 provided by the invention can be incorporated by standard recombinant DNA techniques at the 5' end of a cDNA encoding a mB7-1 protein. The nucleotide sequence of the 5' UT region of mB7-1 (i.e, the full nucleotide sequence of exon 1) is shown in SEQ ID NO: 6.

30 The discovery of additional 5' UT sequences in mB7-1 cDNA demonstrates that transcription of the mB7-1 gene initiates further upstream (i.e., 5') in genomic DNA than previously reported in Selvakumar et al. (*Immunogenetics* (1993) 38:292-295). Transcription of a gene is typically regulated by sequences in genomic DNA located immediately upstream of sequences corresponding to the 5' UT region of the transcribed mRNA. Nucleotides
35 located within approximately 200 base pairs of the start site of transcription are generally considered to encompass the promoter of the gene and often include canonical CCAAT or TATA elements indicative of a typical eukaryotic promoter. For a gene having a promoter which contains a TATA box, transcription usually starts approximately 30 base pairs downstream of the TATA box. In addition to CCAAT and TATA-containing promoters, it is

molecule. For example, mRNA can be prepared from a sample of cells to be examined and the mRNA can be hybridized to an isolated nucleic acid encompassing a nucleotide sequence encoding all or a portion of an alternative cytoplasmic domain of a T cell costimulatory molecule (e.g., SEQ ID NO: 1) to detect the expression of the alternative cytoplasmic domain form of the costimulatory molecule in the cells. Furthermore, the isolated nucleic acids of the invention can be used to design oligonucleotide primers, e.g. PCR primers, which allow one to detect the expression of an alternatively spliced form of a T cell costimulatory molecule. Preferably, this oligonucleotide primer spans a novel exon junction created by alternative splicing and thus can only amplify cDNAs encoding this alternatively spliced form. For example, an oligonucleotide primer which spans exon 4 and exon 6 of murine B7-1 can be used to distinguish between the expression of a first cytoplasmic domain form of mB7-1 (i.e., encoded by exons 1-2-3-4-5) and expression of an alternative second cytoplasmic domain form of a costimulatory molecule (i.e., encoded by exons 1-2-3-4-6) (e.g., see Example 2).

The probes of the invention can be used to detect an alteration in the expression of an alternatively spliced form of a T cell costimulatory molecule, such as in a disease state. For example, detection of a defect in the expression of an alternatively spliced form of a T cell costimulatory molecule that is associated with an immunodeficiency disorder can be used to diagnose the disorder (i.e., the probes of the invention can be used for diagnostic purposes). Many congenital immunodeficiency diseases result from lack of expression of a cell-surface antigen important for interactions between T cells and antigen presenting cells. For example, the bare lymphocyte syndrome results from lack of expression of MHC class II antigens (see e.g., Rijkers, G.T. et al. (1987) *J. Clin. Immunol.* 7:98-106; Hume, C.R. et al. (1989) *Hum. Immunol.* 25:1-11) and X-linked hyperglobulinemia results from defective expression of the ligand for CD40 (gp39) (see e.g. Korthauer, U et al. (1993) *Nature* 361:541; Aruffo, A. et al. (1993) *Cell* 72:291-300). An immunodeficiency disorder which results from lack of expression of an alternatively spliced form of a T cell costimulatory molecule can be diagnosed using a probe of the invention. For example, a disorder resulting from the lack of expression of the Cyt II form of B7-1 can be diagnosed in a patient based upon the inability of a probe which detects this form of B7-1 (e.g., an oligonucleotide spanning the junction of exon 4 and exon 6) to hybridize to mRNA in cells from the patient (e.g., by RT-PCR or by Northern blotting).

B. Recombinant Expression Vectors

An isolated nucleic acid of the invention can be incorporated into an expression vector (i.e., a recombinant expression vector) to direct expression of a novel structural form of a T cell costimulatory molecule encoded by the nucleic acid. The recombinant expression vectors are suitable for transformation of a host cell, and include a nucleic acid (or fragment thereof) of the invention and a regulatory sequence, selected on the basis of the host cells to be used for expression, which is operatively linked to the nucleic acid. Operatively linked is

recombinant protein (Gottesman, S., *Gene Expression Technology: Methods in Enzymology* 185, Academic Press, San Diego, California (1990) 119-128). Another strategy is to alter the nucleic acid sequence of the nucleic acid to be inserted into an expression vector (e.g., a nucleic acid of the invention) so that the individual codons for each amino acid would be those preferentially utilized in highly expressed *E. coli* proteins (Wada et al., (1992) *Nuc. Acids Res.* 20:2111-2118). Such alteration of nucleic acid sequences of the invention can be carried out by standard DNA synthesis techniques and are encompassed by the invention.

Examples of vectors for expression in yeast *S. cerevisiae* include pYepSec1 (Baldari et al., (1987) *Embo J.* 6:229-234), pMFa (Kurjan and Herskowitz, (1982) *Cell* 30:933-943), pJRY88 (Schultz et al., (1987) *Gene* 54:113-123), and pYES2 (Invitrogen Corporation, San Diego, CA). Baculovirus vectors available for expression of proteins in cultured insect cells (SF 9 cells) include the pAc series (Smith et al., (1983) *Mol. Cell Biol.* 3:2156-2165) and the pVL series (Lucklow, V.A., and Summers, M.D., (1989) *Virology* 170:31-39).

Expression of alternatively spliced forms of T cell costimulatory molecules in mammalian cells is accomplished using a mammalian expression vector. Examples of mammalian expression vectors include pCDM8 (Seed, B., (1987) *Nature* 329:840) and pMT2PC (Kaufman et al. (1987), *EMBO J.* 6:187-195). When used in mammalian cells, the expression vector's control functions are often provided by viral material. For example, commonly used promoters are derived from polyoma, Adenovirus 2, cytomegalovirus and Simian Virus 40. The recombinant expression vector can be designed such that expression of the nucleic acid occurs preferentially in a particular cell type. In this situation, the expression vector's control functions are provided by regulatory sequences which allow for preferential expression of a nucleic acid contained in the vector in a particular cell type, thereby allowing for tissue or cell specific expression of an encoded protein.

The recombinant expression vectors of the invention can be a plasmid or virus, or viral portion which allows for expression of a nucleic acid introduced into the viral nucleic acid. For example, replication defective retroviruses, adenoviruses and adeno-associated viruses can be used. The recombinant expression vectors can be introduced into a host cell, e.g. *in vitro* or *in vivo*. A host cell line can be used to express a protein of the invention.

Furthermore, introduction of a recombinant expression vector of the invention into a host cell can be used for therapeutic purposes when the host cell is defective in expressing the novel structural form of the T cell costimulatory molecule. For example, in a recombinant expression vector of the invention can be used for gene therapy purposes in a patient with an immunodeficiency disorder resulting from lack of expression of a novel structural form of a T cell costimulatory molecule.

C. Host Cells

The invention further provides a host cell transfected with a recombinant expression vector of the invention. The term "host cell" is intended to include prokaryotic and

cell is useful for studying signaling events and/or immunological responses which are mediated by the Cyt II domain rather than the Cyt I domain of B7-1. For example, one type of cell which can be used to create a host cell which exclusively expresses the Cyt II-form of murine B7-1 is a non-murine cell, since the non-murine cell does not express murine B7-1.

- 5 Preferably, the non-murine cell also does not express other costimulatory molecules (e.g., COS cells can be used). Alternatively, a mouse cell which does not express the Cyt-I form of murine B7-1 can be used. For example, a recombinant expression vector of the invention can be introduced into NIH 3T3 fibroblast cells (which are B7-1 negative) or into cells derived from a mutant mouse in which the endogenous B7-1 gene has been disrupted and thus which
10 does not natively express any form of B7-1 molecule (i.e., into cells derived from a "B7-1 knock-out" mouse, such as that described in Freeman, G.J. et al. (1993) *Science* 262:907-909).

In another embodiment, the host cell transfected with a recombinant expression vector encoding a novel structural form of a T cell costimulatory molecule is a tumor cell.

- 15 Expression of the Cyt-I form of murine B7-1 on the surface of B7-1 negative murine tumor cells has been shown to induce T cell mediated specific immunity against the tumor cells accompanied by tumor rejection and prolonged protection to tumor challenge in mice (see Chen, L., et al. (1992) *Cell* 71, 1093-1102; Townsend, S.E. and Allison, J.P. (1993) *Science* 259, 368-370; Baskar, S., et al. (1993) *Proc. Natl. Acad. Sci.* 90, 5687-5690). Similarly,
20 expression of novel structural forms of costimulatory molecules on the surface of a tumor cell may be useful for increasing the immunogenicity of the tumor cell. For example, tumor cells obtained from a patient can be transfected *ex vivo* with a recombinant expression vector of the invention, e.g., encoding an alternative cytoplasmic domain form of a costimulatory molecule, and the transfected tumor cells can then be returned to the patient. Alternatively,
25 gene therapy techniques can be used to target a tumor cell for transfection *in vivo*. Additionally, the tumor cell can also be transfected with recombinant expression vectors encoding other proteins to be expressed on the tumor cell surface to increase the immunogenicity of the tumor cell. For example, the Cyt-I form of B7-1, B7-2, MHC molecules (e.g., class I and/or class II) and/or adhesion molecules can be expressed on the
30 tumor cells in conjunction with the Cyt-II form of B7-1.

D. Anti-Sense Nucleic Acid Molecules

- The isolated nucleic acid molecules of the invention can also be used to design anti-sense nucleic acid molecules, or oligonucleotide fragments thereof, that can be used to
35 modulate the expression of alternative forms of T cell costimulatory molecules. An anti-sense nucleic acid comprises a nucleotide sequence which is complementary to a coding strand of a nucleic acid, e.g. complementary to an mRNA sequence, constructed according to the rules of Watson and Crick base pairing, and can hydrogen bond to the coding strand of the nucleic acid. The hydrogen bonding of an antisense nucleic acid molecule to an mRNA

cytoplasmic domain (e.g. Cyt-II) can be made using the isolated nucleic acid shown in SEQ ID NO: 1 or SEQ ID NO: 3. Alternatively, a transgenic animal (e.g., a mouse) which expresses an mB7-2 protein containing an alternative signal peptide domain can be made using the isolated nucleic acid shown in SEQ ID NO: 12. Intronic sequences and polyadenylation signals can also be included in the transgene to increase the efficiency of expression of the transgene. These isolated nucleic acids can be linked to regulatory sequences which direct the expression of the encoded protein one or more particular cell types. Methods for generating transgenic animals, particularly animals such as mice, have become conventional in the art and are described, for example, in U.S. Patent Nos. 4,736,866 and 4,870,009 and Hogan, B. et al., (1986) A Laboratory Manual, Cold Spring Harbor, New York, Cold Spring Harbor Laboratory. A transgenic founder animal can be used to breed additional animals carrying the transgene.

The isolated nucleic acids of the invention can further be used to create a non-human homologous recombinant animal. The term "homologous recombinant animal" as used herein is intended to describe an animal containing a gene which has been modified by homologous recombination. The homologous recombination event may completely disrupt the gene such that a functional gene product can no longer be produced (often referred to as a "knock-out" animal) or the homologous recombination event may modify the gene such that an altered, although still functional, gene product is produced. Preferably, the non-human animal is a mouse. For example, an isolated nucleic acid of the invention can be used to create a homologous recombinant mouse in which a recombination event has occurred in the B7-1 gene at an exon encoding a cytoplasmic domain such that this exon is altered (e.g., exon 5 or exon 6 is altered). Homologous recombinant mice can thus be created which express only the Cyt I or Cyt II domain form of B7-1. Accordingly, the invention provides a non-human knock-out animal which contains a gene encoding a B7-1 protein wherein an exon encoding a novel cytoplasmic domain is disrupted or altered.

To create an animal with homologously recombined nucleic acid, a vector is prepared which contains the DNA sequences which are to replace the endogenous DNA sequences, flanked by DNA sequences homologous to flanking endogenous DNA sequences (see for example Thomas, K.R. and Capecchi, M. R. (1987) *Cell* 51:503). The vector is introduced into an embryonic stem cell line (e.g., by electroporation) and cells in which the introduced DNA has homologously recombined with the endogenous DNA are selected (see for example Li, E. et al. (1992) *Cell* 62:915). The selected cells are then injected into a blastocyst of an animal (e.g., a mouse) to form aggregation chimeras (see for example Bradley, A. in *Teratocarcinomas and Embryonic Stem Cells: A Practical Approach*, E.J. Robertson, ed. (IRL, Oxford, 1987) pp. 113-152). A chimeric embryo can then be implanted into a suitable pseudopregnant female foster animal and the embryo brought to term. Progeny harboring the homologously recombined DNA in their germ cells can be used to breed animals in which all cells of the animal contain the homologously recombined DNA.

embodiment, the isolated protein is a B7-1 or a B7-2 protein. E preferably comprises an amino acid sequence of a murine B7-1 cytoplasmic domain having an amino acid sequence shown in SEQ ID NO: 5 (i.e., the amino acid sequence of the cytoplasmic domain encoded by the novel exon 6 of the invention).

- 5 Another embodiment of the invention provides an isolated protein which binds CD28 or CTLA4 and is encoded by a T cell costimulatory molecule gene having at least one first exon encoding a first cytoplasmic domain and at least one second exon encoding a second cytoplasmic domain. The at least one first cytoplasmic domain comprises an amino acid sequence selected from the group consisting of amino acid sequence of SEQ ID NO:26
10 (mB7-1), SEQ ID NO:28 (hB7-1), SEQ ID NO:30 (mB7-2) and SEQ ID NO:32 (hB7-2). In this embodiment, the protein includes an amino acid sequence comprising at least one second cytoplasmic domain. Preferably, the protein does not include an amino acid sequence comprising a first cytoplasmic domain.

- Preferred proteins which bind CD28 and/or CTLA4 are derived from B7-1 and B7-2.
15 In a particularly preferred embodiment, the invention provides an isolated protein which binds CD28 or CTLA4 and has a novel cytoplasmic domain comprising an amino acid sequence shown in SEQ ID NO: 2.

A. Proteins with a Novel Signal Peptide Domain

- 20 In yet another aspect of the invention, T cell costimulatory molecules which include at least one novel signal peptide domain are provided. In one embodiment, the isolated protein binds to CD28 or CTLA4 and has an amino acid sequence derived from amino acid sequences encoded by at least one T cell costimulatory molecule gene. In this embodiment, the protein comprises a contiguous amino acid sequence represented by a formula A-B-C-D-
25 E, wherein

A comprises an amino acid sequence of a signal peptide domain encoded by at least one exon of a T cell costimulatory molecule gene,

- 30 B comprises an amino acid sequence of an immunoglobulin variable region-like domain encoded by at least one exon of a T cell costimulatory molecule gene,

C comprises an amino acid sequence of an immunoglobulin constant region-like domain encoded by at least one exon of a T cell costimulatory molecule gene,

- D, which may or may not be present, comprises an amino acid sequence of a transmembrane domain encoded by at least one exon of a T cell costimulatory
35 molecule gene, and

E, which may or may not be present, comprises an amino acid sequence of a cytoplasmic domain encoded by at least one exon of a T cell costimulatory molecule gene,

In the formula, A, B, C and D are contiguous amino acid residues linked by amide bonds from an N-terminus to a C-terminus. In a preferred embodiment, an isolated murine B7-1 protein having an IgV-like domain deleted comprises an amino acid sequence shown in SEQ ID NO: 9 (utilizing Cyt I of mB7-1). Alternatively, an isolated murine B7-1 protein having an IgV-like domain deleted comprises an amino acid sequence shown in SEQ ID NO: 11 (utilizing Cyt II of mB7-1).

In another embodiment, the structural form of the T cell costimulatory molecule has at least one IgC-like domain deleted. Accordingly, in one embodiment, the isolated protein has an amino acid sequence derived from amino acid sequences encoded by at least one T cell costimulatory molecule gene and comprises a contiguous amino acid sequence represented by a formula A-B-C-D, wherein

A, which may or may not be present, comprises an amino acid sequence of a signal peptide domain encoded by at least one exon of a T cell costimulatory molecule gene,

B comprises an amino acid sequence of an immunoglobulin variable region-like domain encoded by at least one exon of a T cell costimulatory molecule gene, and

C comprises an amino acid sequence of a transmembrane domain encoded by at least one exon of a T cell costimulatory molecule gene, and

D comprises an amino acid sequence of a cytoplasmic domain encoded by at least one exon of a T cell costimulatory molecule gene.

In the formula, A, B, C and D are contiguous amino acid residues linked by amide bonds from an N-terminus to a C-terminus. In a preferred embodiment, an isolated murine B7-1 protein having an IgC-like domain deleted comprises an amino acid sequence shown in SEQ ID NO: 63 (utilizing Cyt I of mB7-1). Alternatively, an isolated murine B7-1 protein having an IgC-like domain deleted comprises an amino acid sequence shown in SEQ ID NO: 65 (utilizing Cyt II of mB7-1).

The proteins of the invention can be isolated by expression of the molecules (e.g., proteins or peptide fragments thereof) in a suitable host cell using techniques known in the art. Suitable host cells include prokaryotic or eukaryotic organisms or cell lines, for example, yeast, *E. coli* and insect cells. The recombinant expression vectors of the invention, described above, can be used to express a costimulatory molecule in a host cell in order to isolate the protein. The invention provides a method of preparing an isolated protein of the invention comprising introducing into a host cell a recombinant expression vector encoding the protein, allowing the protein to be expressed in the host cell and isolating the protein. Proteins can be isolated from a host cell expressing the protein according to standard procedures of the art, including ammonium sulfate precipitation, fractionation column

T cell costimulatory molecule can be used to inhibit a costimulatory signal in T cells by contacting the T cells with the soluble molecule.

B. Antibodies

- 5 A novel structural form of a T cell costimulatory molecule of the invention can be used to produce antibodies directed against the costimulatory molecule. Conventional methods can be used to prepare the antibodies. For example, to produce polyclonal antibodies, a mammal, (e.g., a mouse, hamster, or rabbit) can be immunized with a costimulatory molecule, or an immunogenic portion thereof, which elicits an antibody
10 response in the mammal. Techniques for conferring immunogenicity on a protein include conjugation to carriers or other techniques well known in the art. For example, the protein can be administered in the presence of adjuvant. The progress of immunization can be monitored by detection of antibody titers in plasma or serum. Standard ELISA or other immunoassay can be used with the immunogen as antigen to assess the levels of antibodies.
15 Following immunization, antisera can be obtained and, if desired, polyclonal antibodies isolated from the sera.

- In addition to polyclonal antisera, the novel costimulatory molecules of the invention can be used to raise monoclonal antibodies. To produce monoclonal antibodies, antibody producing cells (lymphocytes) can be harvested from an immunized animal and fused with
20 myeloma cells by standard somatic cell fusion procedures thus immortalizing these cells and yielding hybridoma cells. Such techniques are well known in the art. For example, the hybridoma technique originally developed by Kohler and Milstein (*Nature* 256, 495-497 (1975)) as well as other techniques such as the human B-cell hybridoma technique (Kozbor et al., *Immunol. Today* 4, 72 (1983)), the EBV-hybridoma technique to produce human
25 monoclonal antibodies (Cole et al. *Monoclonal Antibodies in Cancer Therapy* (1985) Allen R. Bliss, Inc., pages 77-96), and screening of combinatorial antibody libraries (Huse et al., *Science* 246, 1275 (1989)). Hybridoma cells can be screened immunochemically for production of antibodies specifically reactive with the protein or portion thereof and monoclonal antibodies isolated.

- 30 The term antibody as used herein is intended to include fragments thereof which are also specifically reactive with an alternative cytoplasmic domain of a costimulatory molecule. Antibodies can be fragmented using conventional techniques and the fragments screened for utility in the same manner as described above for whole antibodies. For example, F(ab')₂ fragments can be generated by treating antibody with pepsin. The resulting F(ab')₂ fragment
35 can be treated to reduce disulfide bridges to produce Fab' fragments.

Chimeric and humanized antibodies are also within the scope of the invention. It is expected that chimeric and humanized antibodies would be less immunogenic in a human subject than the corresponding non-chimeric antibody. A variety of approaches for making chimeric antibodies, comprising for example a non-human variable region and a human

costimulatory molecule can be stimulated through the costimulatory molecule, e.g., by crosslinking the costimulatory molecules on the cell surface with an antibody, and intracellular signals and/or other cellular changes (e.g., changes in surface expression of proteins etc.) induced thereupon can be identified.

- 5 Additionally, an isolated T cell costimulatory molecule of the invention comprising a novel cytoplasmic domain can be used in methods of identifying other molecules (e.g., proteins) which interact with (i.e., bind to) the costimulatory molecule using standard *in vitro* assays (e.g., incubating the isolated costimulatory molecule with a cellular extract and determining by immunoprecipitation if any molecules within the cellular extract bind to the
- 10 costimulatory molecule). It is of particular interest to identify molecules which can interact with the novel cytoplasmic domain since such molecules may also be involved in intracellular signaling. For example, it is known that the cytoplasmic domains of many cell-surface receptors can interact intracellularly with other members of the signal transduction machinery, e.g., tyrosine kinases.
- 15 The invention further provides a method for screening agents to identify an agent which upregulates or downregulates expression of a novel structural domain form of a T cell costimulatory molecule. The method involves contacting a cell which expresses or can be induced to express a T cell costimulatory molecule with an agent to be tested and determining expression of a novel structural domain form of the T cell costimulatory molecule by the cell.
- 20 The term "upregulates" encompasses inducing the expression of a novel form of a T cell costimulatory molecule by a cell which does not constitutively express such a molecule or increasing the level of expression of a novel form of a T cell costimulatory molecule by a cell which already expresses such a molecule. The term "downregulates" encompasses decreasing or eliminating expression of an a novel form of a T cell costimulatory molecule by
- 25 a cell which already expresses such a molecule. The term "agent" is intended to include molecules which trigger an upregulatory or downregulatory response in a cell. For example, an agent can be a small organic molecule, a biological response modifier (e.g., a cytokine) or a molecule which can crosslink surface structures on the cell (e.g., an antibody). For example, expression of the a novel cytoplasmic domain form of the T cell costimulatory
- 30 molecule by the cell can be determined by detecting an mRNA transcript encoding the novel cytoplasmic domain form of the T cell costimulatory molecule in the cell. For example, mRNA from the cell can be reverse transcribed and used as a template in PCR reactions utilizing PCR primers which can distinguish between a Cyt I cytoplasmic domain form and a novel Cyt II cytoplasmic domain form of the T cell costimulatory molecule (see e.g.,
- 35 Example 2). Alternatively, a novel cytoplasmic domain-containing T cell costimulatory molecule can be detected in the cell using an antibody directed against the novel cytoplasmic domain (e.g., by immunoprecipitation or immunohistochemistry). A preferred T cell costimulatory molecule for use in the method is B7-1. Cell types which are known to express the Cyt-I form of B7-1, or which can be induced to express the Cyt-I form of B7-1, include B

A fusion protein of the invention, comprising a first peptide fused to a second peptide comprising a novel cytoplasmic domain of the invention, can be used to transfer the signal transduction function of the novel cytoplasmic domain to another protein. For example, a novel cytoplasmic domain of B7-1 (e.g., Cyt-II) can be fused to the extracellular and transmembrane domains of another protein (e.g., an immunoglobulin protein, a T cell receptor protein, a growth factor receptor protein etc.) and the fusion protein can be expressed in a host cell by standard techniques. The extracellular domain of the fusion protein can be crosslinked (e.g., by binding of a ligand or antibody to the extracellular domain) to generate an intracellular signal(s) mediated by the novel cytoplasmic domain.

Additionally, a fusion protein of the invention can be used in methods of identifying and isolating other molecules (e.g., proteins) which can interact intracellularly (i.e., within the cell cytoplasm) with a novel cytoplasmic domain of the invention. One approach to identifying molecules which interact intracellularly with the cytoplasmic domain of a cell-surface receptor is to metabolically label cells which express the receptor, immunoprecipitate the receptor, usually with an antibody against the extracellular domain of the receptor, and identify molecules which are co-immunoprecipitated along with the receptor. In the case of mB7-1, however, the cells which have been found to express the naturally-occurring Cyt-II form of B7-1 have also been found to express the naturally-occurring Cyt-I form of B7-1 (e.g., thymocytes, see Example 2). Thus, immunoprecipitation with an antibody against the extracellular domain of mB7-1 would immunoprecipitate both forms of the protein since the extracellular domain is common to both the Cyt-I and Cyt-II containing forms. Thus, molecules which interact with either Cyt-I or Cyt-II would be co-immunoprecipitate. A fusion protein comprising a non-B7-1 extracellular domain (to which an antibody can bind), a transmembrane domain (derived either from the non-B7-1 molecule or from B7-1) and a B7-1 alternative cytoplasmic domain (e.g., Cyt-II) can be constructed and expressed in a host cell which naturally expresses the Cyt-II form of B7-1. The antibody directed against the "heterologous" extracellular domain of the fusion protein can then be used to immunoprecipitate the fusion protein and to co-immunoprecipitate any other proteins which interact intracellularly with the novel cytoplasmic domain.

B. Antibodies

An antibody which binds to a novel structural domain of the invention can be prepared by using the domain, or a portion thereof, as an immunogen. Polyclonal antibodies or monoclonal antibodies can be prepared by standard techniques described above. In a preferred approach, peptides comprising amino acid sequences of the domain are used as immunogens, e.g. overlapping peptides encompassing the amino acid sequence of the domain. For example, polyclonal antisera against a novel cytoplasmic domain (e.g., Cyt II of mB7-1) can be made by preparing overlapping peptides encompassing the amino acid

Genomic cloning

A mouse 129 lambda genomic library was kindly provided by Drs. Hong Wu and Rudolf Jaenisch of the Whitehead Institute for Biomedical Research, Cambridge, MA. Genomic DNA was prepared from the J1 embryonic stem cell line (derived from the 129/sv mouse strain), partially digested with MboI, sized (17-21 kb), and ligated into the BamHI site of lambda-DASH II arms (Stratagene, La Jolla CA). The library was probed with the coding region of mB7-1 cDNA to yield four clones (λ 4, λ 9, λ 15, and λ 16). These lambda clones were subcloned into Bluescript-pKS II (Stratagene, La Jolla CA) for subsequent restriction mapping.

Reverse Transcriptase-Polymerase Chain Reaction (RT-PCR)

Total cellular RNA was prepared from SWR/J mouse spleen and thymus using RNA-Stat-60 (Tel-Test "B", Inc, Friendswood, Texas). Random hexamer primed reverse transcription (RT) was performed with Superscript-RT (Gibco BRL, Gaithersburg MD) using 1-10 μ g total RNA in a 20 μ l reaction. All PCR reactions were performed in 25 μ l volumes using a manual "hot start", wherein 10X deoxynucleotide triphosphates (dNTPs) were added to the samples at 80 °C. Final reaction conditions were: 60 mM Tris-HCl, pH 8.5, 15 mM $(\text{NH}_4)_2\text{SO}_4$, 2.5 mM MgCl_2 , 200 μ M dNTPs, and 2 μ g/ml each of the specific primers. Cycling conditions for all amplifications were 94° C, 4 minutes prior to 35 cycles of 94° C for 45 seconds, 58° C for 45 seconds, and 72° C for 3 minutes, followed by a final extension at 72° C for 7 minutes. The template for primary PCR was 2 μ l of the RT reaction product and the template for secondary nested PCR was 1 μ l of the primary PCR reaction product.

Oligonucleotides

All oligonucleotides were synthesized on an Applied Biosystems 381A DNA Synthesizer. The oligonucleotides used in this study are listed in Table I and their uses for primary or secondary PCR, as well as sense, also are indicated.

Rapid Amplification of cDNA Ends (RACE) Procedure

Polyadenylated RNA purified by two cycles of oligo-dT selection was obtained from CH1 B lymphoma cells, which express high levels of mB7-1. Primers designed to the most 5' end of the cDNA were employed with the 5' RACE Kit (Gibco BRL, Gaithersburg, MD) according to the manufacturer's instructions. In brief, RNA was reverse transcribed with a gene-specific oligonucleotide, the cDNA purified, and a poly-dCTP tail was added with terminal deoxynucleotide transferase. PCR was performed using a nested primer and an oligonucleotide complimentary to the poly-dCTP tail. PCR bands were cloned, sequenced, and correlated with the genomic sequences.

EXAMPLE 2: Identification of mB7-1 exon 6: An alternately spliced exon encoding a novel second cytoplasmic domain

Analysis of mB7-1 cDNAs isolated from an A20 B cell cDNA library showed that one cDNA contained additional sequence not previously described for the mB7-1 cDNA.

- 5 This sequence was mapped to the mB7-1 locus approximately 7-kb downstream of exon 5. A canonical splice site was present immediately upstream of this sequence and a poly-adenylation site was present downstream. Taken together, these data suggested that this novel sequence represents an additional exon, encoding 46 amino acids, which may be alternatively spliced in place of exon 5. This alternative cytoplasmic domain is notable for
- 10 two casein kinase II phosphorylation sites (amino acid positions 11-15 (SAKDF) and amino acid positions 28-32 (SLGEA) of SEQ ID NO: 5) (for a description of casein kinase II phosphorylation sites see Pinna (1990) *Biochimica et Biophysica Acta* 1054:267-284) and one protein kinase C phosphorylation site (amino acid positions 11-14 (SAKD) of SEQ ID NO: 5)(for a description of protein kinase C phosphorylation sites see Woodgett et al. (1986)
- 15 *Biochemistry* 161:177-184; and Kishimoto et al. (1985) *J. Biol. Chem.* 260:12492-12499).

- In order to assess whether exon 6 also could be used in an alternative fashion, an antisense primer (B7.48) was designed to the predicted exon 4/6 splice junction such that only the alternatively spliced product would give rise to an amplified product. This primer overhangs the putative exon 4/6 junction by 3 bp at its 3' end. The 3 bp overhang is
- 20 insufficient to permit direct priming in exon 4 outside the context of an exon 4/6 splice (Figure 1, lane 9, negative control is a cDNA clone containing only mB7-1 CytI). The expected amplified product for the alternately spliced transcript (Figure 1, transcript C) would be 399 bp. Interestingly, this transcript was observed only in thymic, but not splenic RNA.

- 25 [In Figure 1, lanes 1, 2 and 3 represent nested PCR products from murine splenic RNA using PCR primers B7.27-B7.36, B7.27-B7.38, and B7.27-B7.48, respectively. Lanes 4, 5 and 6 represent nested PCR products from murine thymic RNA using PCR primers B7.27-B7.36, B7.27-B7.38 and B7.27-B7.48, respectively. Lane 7 represents a negative control (no input RNA). Lane 8 represents a positive control (mB7-1 cDNA clone). Lane 9 represents a
- 30 negative control for B7.27-B7.48 amplification comprised of the mB7-1 cDNA containing cytoplasmic domain I, which does not have the correct exon 4-6 splice junction. Lane M is a 100 bp ladder with the lower bright band equal to 600 bp. Letters A, B and C refer to the transcripts detected and are further illustrated in Figure 1. Note that exon 6 splicing as an alternative cytoplasmic domain is present only in the thymus, but not in the spleen].

- 35 To further investigate the use of exon 6 in mB7-1 mRNA transcripts, nested RT-PCR spanning exons 3 through 6 was performed using spleen RNA (Figure 1, PCR product A). A PCR product longer than predicted from the use of exon 6 as an alternatively spliced exon also was observed. Subsequent sequence analysis indicated that in this transcript, exons 5 and 6 were spliced in tandem, rather than in an alternative fashion (Figure 1, transcript A),

junctions have been reported previously (Selvakumar et al. (1993) *Immunogenetics* 38:292-295). The coding region of the exon 1 signal peptide domain is 115 bp and is flanked at the 3' end with a canonical splice site. Exons 2 (318 bp), 3 (282 bp), and 4 (114 bp), are separated by 6.0 and 3.8 kb, respectively, and all 3 exons are flanked on both their 5' and 3' ends with canonical splice sites. Exon 5 is located 4 kb downstream of exon 4, and contains a termination codon after the first 97 bp. An additional functional canonical splice site was observed 43 bp downstream of the termination codon in exon 5, since this site was used to generate the transcript outlined in Figure 1 (transcript A). Exon 6 is located 7.2 kb downstream of exon 5 and encodes an open reading frame with a termination codon after 140 bp. Both exons 5 and 6 are followed by polyadenylation sequences, ATTAAA and AATAAA respectively.

EXAMPLE 5: Identification of Additional Novel Cytoplasmic Domains by Exon Trapping

In this example, an exon trapping approach is used to identify a novel exon encoding an alternative cytoplasmic domain for human B7-1. The basic strategy of exon trapping is to create an expression vector encoding a recombinant protein, wherein the encoded protein cannot be functionally expressed unless an appropriate exon, with flanking intron sequences that allow proper mRNA splicing, is cloned into the expression vector. A recombinant expression vector is created comprising transcriptional regulatory sequences (e.g., a strong promoter) linked to nucleic acid encoding the human B7-1 signal peptide exon, IgV-like and IgC-like exons followed by a transmembrane exon with flanking 3' intron donor splice sequences. These splice sequences are immediately followed by translational stop codons in all three frames. A polyadenylation recognition site is not included in the recombinant expression vector. Following the stop codons are restriction enzyme sites which allow genomic DNA fragments to be cloned into the expression vector to create a library of recombinant expression vectors.

As a negative control, the parental recombinant expression vector is transfected into a host cell line which is hB7-1⁻ (e.g., COS cells) and the absence of surface expression of hB7-1 is demonstrated, confirming that the parental expression vector alone is unable to direct stable surface expression of hB7-1 in the absence of a cytoplasmic domain encoding exon. As a positive control, the known hB7-1 cytoplasmic domain with a flanking 5' intron acceptor splice sequence is cloned into a restriction enzyme site downstream of the transmembrane exon such that the transmembrane domain exon can be spliced to the cytoplasmic domain exon. This positive control vector is transfected into a host cell (e.g., COS cells) and the surface expression of hB7-1 on the cells is demonstrated, confirming that the cloning into the vector of a cytoplasmic domain encoding exon with the proper splice sequences produces an hB7-1 molecule that can be stably expressed on the cell surface.

complementary to the poly-dCTP tail to amplify 5' cDNA fragments of mB7-2 transcripts. The gene-specific oligonucleotide primers used for PCR were as follows:

- 5 CAGCTCACTCAGGCTTATGT reverse transcription, - sense (SEQ ID NO: 55)
- AAACAGCATCTGAGATCAGCA primary PCR, - sense (SEQ ID NO: 56)
- CTGAGATCAGCAAGACTGTC secondary PCR, - sense (SEQ ID NO: 57)

- 10 The amplified fragments were subcloned into a plasmid vector and sequenced. Of approximately 100 individual clones examined, ~75 % of the clones had a 5' nucleotide sequence corresponding to that reported for the 5' end of an mB7-2 cDNA (see Freeman, G.J. et al. (1993) *J. Exp. Med.* 178:2185-2192). Approximately 25 % of the clones had a 5' nucleotide sequence shown in SEQ ID NO:14, which encodes a novel signal peptide domain
- 15 having an amino acid sequence shown in SEQ ID NO:15.

**EXAMPLE 7: Identification of Alternatively Spliced Forms of B7-1
Having a Structural Domain Deleted**

- 20 Reverse-transcriptase polymerase chain reaction was used to amplify mB7-1 cDNA fragments derived from murine spleen cell RNA. Oligonucleotide primers used for PCR were as follows:

- CTGAAGCTATGGCTTGCAATT primary PCR, + sense (SEQ ID NO: 58)
- 25 ACAAGTGCTTCAGATGTTGAT secondary PCR, + sense (SEQ ID NO: 59)
- CTGGATTCTGACTCACCTTCA primary PCR, - sense (SEQ ID NO: 60)
- CCAGGTGAAGTCCTCTGACA secondary PCR, - sense (SEQ ID NO: 61)
- 30

A cDNA fragment was detected which comprises a nucleotide sequence (SEQ ID NO:8) encoding a murine B7-1 molecule in which the signal peptide domain was spliced directly to the IgC-like domain (i.e., the IgV-like domain was deleted). The amino acid sequence of mB7-1 encoded by this cDNA is shown in SEQ ID NO:9.

- 35 Another cDNA fragment was detected with comprises a nucleotide sequence (SEQ ID NO: 62) encoding a murine B7-1 molecule in which the IgV-like domain was spliced directly to the transmembrane domain (i.e., the IgC-like domain was deleted). The amino acid sequence encoded by this cDNA is shown in SEQ ID NO: 63). This protein is referred to herein as an IgV-like isoform of mB7-1. To examine the functional activity of the IgV-like

CLAIMS

1. An isolated nucleic acid encoding a protein which binds CD28 or CTLA4 comprising a contiguous nucleotide sequence derived from at least one T cell costimulatory molecule gene, the nucleotide sequence represented by a formula A-B-C-D-E, wherein

A comprises a nucleotide sequence of at least one first exon of a T cell costimulatory molecule gene, wherein the at least one first exon encodes a signal peptide domain,

- 10 B comprises a nucleotide sequence of at least one second exon of a T cell costimulatory molecule gene, wherein the at least one second exon encodes an immunoglobulin variable region-like domain,

- 15 C comprises a nucleotide sequence of at least one third exon of a T cell costimulatory molecule gene, wherein the at least one third exon encodes an immunoglobulin constant region-like domain,

D comprises a nucleotide sequence of at least one fourth exon of a T cell costimulatory molecule gene, wherein the at least one fourth exon encodes a transmembrane domain, and

- 20 E comprises a nucleotide sequence of at least one fifth exon of a T cell costimulatory molecule gene, wherein the at least one fifth exon encodes a cytoplasmic domain,

with the proviso that E does not comprise a nucleotide sequence selected from a group consisting of SEQ ID NO:25, SEQ ID NO:27, SEQ ID NO:29 and SEQ ID NO:31.

25

2. The isolated nucleic acid of claim 1 which is a cDNA.

3. The isolated nucleic acid of claim 2 which comprises a coding region of the cDNA.

30

4. The isolated nucleic acid of claim 1, wherein the nucleotide sequence is derived from a T cell costimulatory molecule gene encoding B7-1.

5. The isolated nucleic acid of claim 4, wherein B7-1 is murine.

35

6. The isolated nucleic acid of claim 4, wherein B7-1 is human.

7. The isolated nucleic acid of claim 5, wherein E comprises a nucleotide sequence shown in SEQ ID NO:4.

18. An isolated protein which binds to CD28 or CTLA4 having an amino acid sequence derived from amino acid sequences encoded by at least one T cell costimulatory molecule gene, the protein comprising a contiguous amino acid sequence represented by a formula A-B-C-D-E, wherein

5

A, which may or may not be present, comprises an amino acid sequence of a signal peptide domain encoded by at least one exon of a T cell costimulatory molecule gene,

10

B comprises an amino acid sequence of an immunoglobulin variable region-like domain encoded by at least one exon of a T cell costimulatory molecule gene,

C comprises an amino acid sequence of an immunoglobulin constant region-like domain encoded by at least one exon of a T cell costimulatory molecule gene,

D comprises an amino acid sequence of a transmembrane domain encoded by at least one exon of a T cell costimulatory molecule gene, and

15

E comprises an amino acid sequence of a cytoplasmic domain encoded by at least one exon of a T cell costimulatory molecule gene,

with the proviso that E not comprise an amino acid sequence selected from the group consisting of SEQ ID NO:26, SEQ ID NO:28, SEQ ID NO:30 and SEQ ID NO:32.

20

19. The isolated protein of claim 18 which is B7-1.

20. The isolated protein of claim 19 which is murine.

25

21. The isolated protein of claim 19 which is human.

22. The isolated protein of claim 20, wherein E comprises an amino acid sequence shown in SEQ ID NO:5.

30

23. An isolated protein which binds CD28 or CTLA4 and is encoded by a T cell costimulatory molecule gene having

at least one first exon encoding a first cytoplasmic domain comprising an amino acid sequence selected from the group consisting of an amino acid sequence of SEQ ID NO:26, SEQ ID NO:28, SEQ ID NO:30, and SEQ ID NO:32, and

35

at least one second exon encoding a second cytoplasmic domain, wherein the T cell costimulatory molecule comprises the second cytoplasmic domain.

24. The isolated protein of claim 23 which does not comprise the first cytoplasmic domain.

E, which may or may not be present, comprises a nucleotide sequence of at least one fifth exon of a T cell costimulatory molecule gene, wherein the at least one fifth exon encodes a cytoplasmic domain,

5 with the proviso that A does not comprise a nucleotide sequence selected from a group consisting of SEQ ID NO:33, SEQ ID NO:35, SEQ ID NO:37, SEQ ID NO:39 and SEQ ID NO:41.

10 34. The isolated nucleic acid of claim 33 which is a cDNA.

35. The isolated nucleic acid of claim 34 which comprises a coding region of the cDNA.

15 36. The isolated nucleic acid of claim 33, wherein the nucleotide sequence is derived from a T cell costimulatory molecule gene encoding B7-2.

37. The isolated nucleic acid of claim 36, wherein B7-2 is murine.

20 38. The isolated nucleic acid of claim 36, wherein B7-2 is human.

39. The isolated nucleic acid of claim 37, wherein A comprises a nucleotide sequence shown in SEQ ID NO:14.

25 40. An isolated nucleic acid encoding a protein which binds CD28 or CTLA4 and is encoded by a T cell costimulatory molecule gene having

at least one first exon encoding a first signal peptide domain comprising a nucleotide sequence selected from the group consisting of a nucleotide sequence of SEQ ID NO:33, SEQ ID NO:35, SEQ ID NO:37 SEQ ID NO:39 and SEQ ID NO:41, and

30 at least one second exon encoding a second signal peptide domain, wherein the isolated nucleic acid comprises a nucleotide sequence encoding the second signal peptide domain.

41. The isolated nucleic acid of claim 40 which comprises a coding region of a cDNA.

35 42. The isolated nucleic acid of claim 40 which does not comprise a nucleotide sequence encoding the first signal peptide domain.

51. The isolated protein of claim 49 which is human.
52. The isolated protein of claim 50, wherein A comprises an amino acid sequence
5 shown in SEQ ID NO: 15.
53. An isolated protein which binds CD28 or CTLA4 and is encoded by a T cell
costimulatory molecule gene having
at least one first exon encoding a first signal peptide domain comprising an amino
10 acid sequence selected from the group consisting of an amino acid sequence of SEQ ID
NO:34, SEQ ID NO:36, SEQ ID NO:38, SEQ ID NO:40 and SEQ ID NO:42, and
at least one second exon encoding a second signal peptide domain,
wherein the T cell costimulatory molecule comprises the second signal peptide domain.
- 15 54. The isolated protein of claim 53 which does not comprise the first signal
peptide domain.
55. The isolated protein of claim 53 which is B7-2.
- 20 56. The isolated protein of claim 55 which is murine.
57. The isolated protein of claim 55 which is human.
58. An isolated protein which binds CD28 or CTLA4 comprising an amino acid
25 sequence shown in SEQ ID NO:13.
59. An isolated signal peptide domain polypeptide derived from a protein which
binds CD28 or CTLA4, the polypeptide comprising an amino acid sequence shown in SEQ
ID NO:15.
30
60. A recombinant expression vector comprising the nucleic acid molecule of
claim 46.
61. A host cell which contains the recombinant expression vector of claim 60.
35
62. An antibody which binds to the polypeptide of claim 59.

68. The isolated protein of claim 66 comprising an amino acid sequence shown in SEQ ID NO:11.

5 69. An isolated nucleic acid encoding a protein comprising a contiguous nucleotide sequence derived from at least one T cell costimulatory molecule gene, the nucleotide sequence represented by a formula A-B-C-D, wherein

10 A comprises a nucleotide sequence of at least one first exon of a T cell costimulatory molecule gene, wherein the at least one first exon encodes a signal peptide domain,

B comprises a nucleotide sequence of at least one second exon of a T cell costimulatory molecule gene, wherein the at least one second exon encodes an immunoglobulin variable region-like domain,

15 C comprises a nucleotide sequence of at least one third exon of a T cell costimulatory molecule gene, wherein the at least one third exon encodes a transmembrane domain, and

20 D comprises a nucleotide sequence of at least one fourth exon of a T cell costimulatory molecule gene, wherein the at least one fourth exon encodes a cytoplasmic domain.

70. The isolated nucleic acid of claim 69 comprising a nucleotide sequence shown in SEQ ID NO:62.

25 71. The isolated nucleic acid of claim 69 comprising a nucleotide sequence shown in SEQ ID NO:64.

30 72. An isolated protein having an amino acid sequence derived from amino acid sequences encoded by at least one T cell costimulatory molecule gene, the protein comprising a contiguous amino acid sequence represented by a formula A-B-C-D, wherein

A, which may or may not be present, comprises an amino acid sequence of a signal peptide domain encoded by at least one exon of a T cell costimulatory molecule gene,

35 B comprises an amino acid sequence of an immunoglobulin variable region-like domain encoded by at least one exon of a T cell costimulatory molecule gene, and

C comprises an amino acid sequence of a transmembrane domain encoded by at least one exon of a T cell costimulatory molecule gene, and
